ABSTRACT

Background: Febrile seizures are disorders that arise due to an abnormal increase in body temperature (temperature $>38^{\circ}\text{C}$). Febrile seizures can cause serious complications, including epilepsy, hemiparesis, brain trauma, mental retardation due to severe brain damage, physical disabilities, behavioral disorders, learning disorders, and even death. **Research Objective:** to provide nursing care and analyze the results between theory and facts in toddlers with febrile seizures in the Dahlia Room of Dr. Soedomo Trenggalek Regional General Hospital. **Research Method:** This study uses a qualitative descriptive design with a case study method. Participants in this study were one client aged 2 years and 2 months who experienced seizures and accompanied by an increase in temperature with composmentis consciousness without comorbidities. The location of the study was in the Dahlia Room of Dr. Soedomo Trenggalek Regional General Hospital. Data analysis was carried out by comparing the gap between theory and facts. **Research Results:** discrepancies were found in the family health history, developmental history, immunization history, elimination patterns (BAB), rest patterns, eye and heart examination. The diagnoses that emerged included hyperthermia related to the disease process (infection) and airway clearance related to retained secretions. The interventions used were in accordance with the existing literature study theory. Implementation was carried out based on the interventions that had been prepared and adjusted to the client's problems. Nursing evaluation was carried out for three days with the criteria for the results of the problem being resolved, the client showing an increase in health status. **Conclusion:** Clients with febrile seizures require special supervision to achieve optimal recovery. Therefore, adequate information and appropriate actions are essential in providing nursing care to clients with febrile seizures.
